Abstract Twenty-eight species belonging to 12 genera in 7 families of crustacean Anomura were recorded from the northern Mariana Islands. These include 1 species of Callianassidae, 6 species of Coenobitidae, 9 species of Diogenidae, 3 species of Paguridae, 1 species of Galatheidae, 7 species of Porcellanidae and 1 species of Hippidae. All species of Callianassidae, Paguridae, Galatheidae and Hippidae are records from the northern Marianas for the first time.

Key words: Crustacea, Anomura, rocky intertidal, subtidal, Mariana.

In May and June 1992, the Natural History Museum and Institute, Chiba (NHMIC) organized the expedition to the northern Mariana Islands, Micronesia, in cooperation with the Department of the Natural Resources (Commonwealth of the Northern Mariana Islands) and the University of Guam Marine Laboratory. In this paper, the anomuran crustaceans collected by the research members are reported. Anomuran fauna of the northern Marianas have been partly revealed, such as hermit crabs of genus *Calcinus* (Wooster, 1982) and of porcelain crabs of genus *Petrolisthes* (Haig and Kropp, 1987; Kropp, 1983, 1987). Remaining taxa has been largely unstudied, and, in the following list, there are a considerable number of species recorded for the first from the northern Marianas.

Methods

The islands investigated were, from north to south, Uracas, Maug North, Maug East, Maug West, Asuncion, Agrihan, Pagan, Alamagan, Guguan, Sarigan, and Anatahan (see Asakura *et al.*, 1994, for detailed map and location of the sampling stations). Most of the specimens were collected in the rocky intertidal areas of the islands, such collection sites being abbreviated as RI in the following list. Collections were also made by SCUBA and skin divers in the subtidal areas, and depth of the collection site was recorded. Collectors (and their initials used in

the list) were Akira Asakura (AA), Taiji Kurozumi (TK) and Hiroshi Harada (HH) of the NHMIC, and Todd Pitlick (TP) of the University of Guam Marine Laboratory. All of the specimens were deposited at the NHMIC, and CBM-ZC is the registration code for crustaceans. Identification was made by Akira Asakura for the families Callianassidae, Coenobitidae, Diogenidae, Porcellanidae and Hippidae, Tomoyuki Komai for the Paguridae, and Keiji Baba of Kumamoto University for the Galatheidae. For representing size of each individual, following measurements are used for each respective taxa; shield length (SL) for hermit crabs (Coenobitidae, Diogenidae, and Paguridae), carapace length (CL) for ghost shrimp (Callianassidae) and mole crab (Hippidae), carapace width (CW) and length (CL) for porcelain crabs (Porcellanidae). Measurements were done to the nearest 0.1 mm with dial calipers or micrometer, being given in the parenthesis in the text in mm. The arrangement of taxa follows McLaughlin (1980). All of shells inhabited by hermit crabs were identified by T. Kurozumi.

16. *Diogenes* sp.

Material examined. 1 ind. MAUG EAST-st. B, diving, 3 m deep. CBM-ZC-1609.

Remarks. The specimen is badly damaged and can not be identified. Since, in this species, the antennal peduncle is distinctly shorter than the ocular peduncle, it should be placed to the "gardineri-group" (Forest, 1957).

19. *Pagurixus* cf. *tweediei* (Forest)

Material examined. 4♂(SL=1.8–2.6 mm), MAUG EAST-st.A, RI, 2 June, AA, CBM-ZC-1615; 3♂(1.2–1.7), 10♀(1.7–2.1), 1ovig.♀(1.7), MAUG WEST-st.E, 4 June, AA, CBM-ZC-1616.

Shell. *Cerithium nesioticum* Pilsbry and Vanatta, *Cerithium atrormarginatum* (Dautzenberg and Bouge), *Angiola labiosa* (A. Adams), *Supplanaxis nigra* (Quoy and Gaimard), *Littoraria pintado* (Wood), *Morula uva* (Röding), *Cronia fusconigra* (Pease), *Reticunassa pauperus* (Gould).

Distribution. Known with certainty only from Cocos-Keeling Islands (Forest, 1956). Subsequently McLaughlin and Haig (1984) recorded a male specimen from Philippines as *Pagurixus* cf. *tweediei*.

Remarks. Following key to the species of *Pagurixus* given by McLaughlin and Haig (1984), the present Mariana specimens are identified to *Pagurixus tweediei* (Forest), which has been known only by the original description (Forest, 1956) and the subsequent record by McLaughlin and Haig (1984). A few minor differences are apparent between the present Mariana specimens and the original description of *P. tweediei*. The chela of the right cheliped is relatively broader in the present male specimens than in the figured male of syntypes of *P.*

tweediei (1.2 times as long as wide vs. 2.0 times as long). The spine on the dorsodistal margin of the merus of the right cheliped described for the syntypes of *P. tweediei* is not present on our specimens. The dactyl of the left second pereopod is relatively shorter in the present specimens than in the figured syntype (0.8 times as long as propodus vs. 0.9 times as long). Moreover, our Mariana specimens are different from the description of a male specimen assigned to *P. tweediei* with a little doubt by McLaughlin and Haig (1984) in the following respects; delimitations of the dorsomesial and dorsolateral margins of the right palm described for the specimen of McLaughlin and Haig (1984) are absent in the male specimens of the present material, though weak delimitations are sometimes found in the females; the telson is relatively wider with broadly rounded terminal margins, rather than obliquely concave. It is difficult at present to determine whether these differences fall within range of variation of the species, since very little specimens have been described for *P. tweediei*. To establish the status of our Mariana specimens, direct comparison with the syntypes and the specimen described by McLaughlin and Haig (1984) and additional material from various localities are strongly needed.
